Burgueño, R., García-González, L., Abós, Á., & Sevil-Serrano, J. (2023). Students' need satisfaction and frustration profiles: Differences in outcomes in physical education and physical activity-related variables. *European Physical Education Review*, 29(4), 563–581. <https://doi.org/10.1177/1356336X231165229>

**Students' need satisfaction and frustration profiles: differences in outcomes in physical education and physical activity-related variables**

## Abstract

Grounded in self-determination theory, the objectives of the present research were to identify latent profiles based on need-based experiences in physical education (PE), and to examine differences in outcomes in PE (i.e. motivation, experiences, and oppositional defiance) and physical activity-related variables **outside** of PE (i.e. physical activity intention, moderate-to-vigorous physical activity, and meeting physical activity recommendations) across the identified profiles. A purposive sample of 1062 secondary PE students (526 boys and 536 girls;  $M_{age}=14.15$ ,  $SD=1.51$ ) participated in this cross-sectional study. Results from latent profile analysis revealed four need satisfaction and frustration profiles: “high need satisfaction–low need frustration”; “moderate need satisfaction–low need frustration”; “moderate need satisfaction–**moderate need** frustration”; and “low need satisfaction–high need frustration”. For outcomes **in** PE, the “high need satisfaction–low need frustration” profile was the most adaptive, while the “low need satisfaction–high need frustration” profile obtained the most maladaptive pattern of outcomes. The “moderate need satisfaction–low need frustration” profile was more adaptive than “moderate need satisfaction–**moderate need** frustration” profile, although both were similar in experiences and oppositional defiance. For physical activity-related outcomes **outside of** PE, the “high need satisfaction–low need frustration” profile scored highest, while no differences were obtained among the three remaining profiles. These results provide further insight into the importance for PE teachers not only to support students’ need satisfaction, but also to minimize need frustration, in obtaining the most optimal pattern of outcomes in PE, as well as a more active lifestyle among students.

Keywords: Autonomy, competence, relatedness, physical activity, behavioral regulation.

## Introduction

It is widely known that physical activity (PA) is related to physical, psychological, and social benefits in youth (García-Hermoso et al., 2021). However, the **most recent** global prevalence report showed that 77.60% of male and 84.70% of female youth fail to **engage in** at least 60 minutes of daily moderate-to-vigorous physical activity (MVPA) (Guthold et al., 2020). In light of **this situation** of **global physical inactivity**, physical education (PE) represents a potentially suitable context to effectively promote MVPA inside (Hollis et al., 2017) and outside the lessons, by providing students with the knowledge, abilities, and values necessary **for lifelong** participation (SHAPE America—Society of Health and Physical Educators, 2014). According to self-determination theory (SDT; Ryan and Deci, 2020), one of the most determining factors in fostering positive consequences **for** PE and PA behavior change in young people is the perception of basic psychological needs (**BPNs**) in PE lessons (Vasconcellos et al., 2020).

SDT (Ryan and Deci, 2020) conceptualizes autonomy, competence, and relatedness as **BPNs** for optimal growth and wellness. This theory of human behavior draws a clear distinction between need satisfaction and need frustration, arguing that each person (e.g. student) can experience both perceptions within the same context (e.g. PE) with each differently yielding specific outcomes (Vansteenkiste et al., 2020). However, in PE, most **previous** studies adopted variable-centered approaches (e.g. structural equation modeling, regression analysis) to analyze the relationship between need satisfaction and/or need frustration and different outcomes **in and outside** of PE (Haerens et al., 2015; Vasconcellos et al., 2020). To the best of our knowledge, there is one single study that took a person-centered analysis (e.g. latent profile analysis) in PE to examine the association of different students' need satisfaction and frustration profiles with motivation for PE (Warburton et al., 2020), but not with other outcomes **in and outside of**

1  
2  
3 76 PE. Therefore, the question of which configuration of need satisfaction and need  
4  
5 77 frustration yields the most and the least desirable outcomes has received little attention in  
6  
7  
8 78 PE. The present research adopts a person-centered approach to expand  
9  
10 79 previous knowledge of the differences between students' autonomy, competence, and  
11  
12 80 relatedness need satisfaction and frustration profiles in PE and outcomes in (i.e. quality  
13  
14 81 of motivation, experiences, and oppositional defiance) and outside of (i.e. PA intention,  
15  
16 82 MVPA levels, and meeting PA recommendations) PE.

### 19 83 **BPNs theory in physical education**

21 84 SDT conceptualizes the BPNs for autonomy, competence, and relatedness as the  
22  
23 85 essential nutrients for adjustment, growth, and wellness (Ryan and Deci, 2020). This  
24  
25 86 theoretical framework postulates a dual-process model in explaining human functioning  
26  
27 87 by drawing a bright and dark pathway based on the distinction between the satisfaction  
28  
29 88 and the frustration of the three BPNs (Vansteenkiste et al., 2020). While need satisfaction  
30  
31 89 represents the core of the bright pathway of functioning, as it would contribute to  
32  
33 90 proactivity, integration, and wellness, need frustration constitutes the dark pathway of  
34  
35 91 functioning, since it would be prone to passivity, fragmentation, and illness (Ryan et al.,  
36  
37 92 2021; Vansteenkiste et al., 2020). Autonomy satisfaction concerns the experience of  
38  
39 93 initiative and choice of behaviors, whereas autonomy frustration involves being forced to  
40  
41 94 behave in a prescribed manner. Competence satisfaction concerns mastery and capacity  
42  
43 95 to meet expected challenges, whereas competence frustration involves inefficacy and  
44  
45 96 failure to achieve desired goals. Finally, relatedness satisfaction concerns belonging and  
46  
47 97 genuine connections with valued others, whereas relatedness frustration involves  
48  
49 98 loneliness and exclusion from significant others.

55  
56 99 SDT-based research has broadly shown in different contexts that need satisfaction  
57  
58 100 and need frustration may co-occur to different degrees, rather than being two opposite  
59  
60

1  
2  
3 101 poles along a need-fulfilment continuum. Both are characterized by distinct psychological  
4  
5 102 experiences and are related to different antecedents and consequences (Ryan et al., 2021;  
6  
7 103 Vansteenkiste et al., 2020). **In particular, research has well documented that low levels of**  
8  
9 104 **need satisfaction were consistently associated with feelings of low wellness, but not**  
10  
11 105 **necessarily with experiences of illness, whereas need frustration was robustly related to**  
12  
13 106 **illness and malfunctioning** (Ryan et al., 2021; Vansteenkiste et al., 2020). For example, a  
14  
15 107 student who feels low need satisfaction in PE lessons might perceive fewer opportunities  
16  
17 108 than **he/she** desired to choose, not be as good as expected at task completion or display  
18  
19 109 indifferent links with his/her classmates. Instead, another student who experiences need  
20  
21 110 frustration in PE lessons may feel compelled to act as the teacher directs, incompetent,  
22  
23 111 and excluded by his/her peers. Hence, the relationship between low need satisfaction and  
24  
25 112 the presence of need frustration is believed to be asymmetrical (Ryan et al., 2021;  
26  
27 113 Vansteenkiste et al., 2020). In other words, low levels of need satisfaction do not  
28  
29 114 necessarily imply the presence of need frustration, as they do not adequately capture the  
30  
31 115 active nature that defines any experience of need frustration, whereas need frustration  
32  
33 116 **entails** low need satisfaction (Ryan et al., 2021; Vansteenkiste et al., 2020). **Consequently,**  
34  
35 117 SDT proposes that need satisfaction and need frustration can simultaneously interact  
36  
37 118 within the same context, with each being related differently to specific antecedents and  
38  
39 119 outcomes (Ryan et al., 2021).

40  
41  
42 120 In the PE context, a substantial body of research **has** gathered support for the bright  
43  
44 121 pathway with positive relationships between students' need satisfaction in PE and an  
45  
46 122 array of adaptive consequences, including autonomous motivation (i.e. behavior is  
47  
48 123 undertaken **for** inherent enjoyment, inclusion in the student's lifestyle or the benefits  
49  
50 124 derived), and positive PE experiences (Behzadnia, 2021; **García-González et al., 2019;**  
51  
52 125 Haerens et al., 2015, 2019; Leo et al., 2022; Tilga et al., 2020; Vasconcellos et al., 2020).

1  
2  
3 126 Furthermore, previous research has evidenced a dark pathway with positive relationships  
4  
5 127 between students' need frustration and a range of maladaptive outcomes, including  
6  
7 128 controlled motivation (i.e. behavior is undertaken by coercion and self-imposed or  
8  
9 129 external pressures), amotivation (i.e. the total absence of volition toward the behavior),  
10  
11 130 and oppositional defiance in PE (i.e. a forceful resistance against the teacher's authority)  
12  
13 131 (Abós et al., 2022; Behzadnia, 2021; García-González et al., 2019; Haerens et al., 2015,  
14  
15 132 2019; Leo et al., 2022; Tilga et al., 2020; Vasconcellos et al., 2020).

16  
17  
18  
19 133 Previous studies in PE have also suggested a “buffering role” (cross-path) of need  
20  
21 134 satisfaction against maladaptive outcomes. In this line, negative but weaker associations  
22  
23 135 of need satisfaction with controlled motivation, amotivation, and oppositional defiance  
24  
25 136 have been found (García-González et al., 2019; Haerens et al., 2015, 2019; Leo et al.,  
26  
27 137 2022). Similarly, need frustration has been found to play a “hampering role” (cross-path)  
28  
29 138 on adaptive outcomes. Thus, negative and weaker relationships between need frustration  
30  
31 139 and autonomous motivation in PE have been found (García-González et al., 2019;  
32  
33 140 Haerens et al., 2015, 2019; Leo et al., 2022).

34  
35  
36  
37 141 On the other hand, little is known about the trans-contextual effects of students'  
38  
39 142 need satisfaction and frustration in PE on PA-related variables outside this context.  
40  
41 143 Specifically, the trans-contextual model of motivation holds the premise that autonomy,  
42  
43 144 competence, and relatedness satisfaction in the PE context may transfer to need  
44  
45 145 satisfaction in a similar context (i.e. PA context) (Barkoukis et al., 2010; González-Cutre  
46  
47 146 et al., 2014). Previous research has found a positive relationship between students' need  
48  
49 147 satisfaction in PE and PA intention (i.e. the degree of willingness to continue PA behavior  
50  
51 148 for at least a few months) (Di Battista et al., 2019) and MVPA levels (Gråstén et al.,  
52  
53 149 2021). A negative relationship between students' need frustration in PE and PA-related  
54  
55 150 outcomes has also been found in the few existing studies (Koka et al., 2019, 2020).

### 151 **Need satisfaction and frustration profiles**

152 Much of the previous research on PE adopted variable-centered approaches to  
153 examine the relationship of students' need satisfaction and/or frustration to different  
154 outcomes **in and outside of** PE (Vasconcellos et al., 2020). These variable-centered  
155 analyses (e.g. structural equation modeling, regression analysis) do not allow us to know  
156 whether people can perceive several variables simultaneously and what differences exist  
157 between these various combinations (i.e. profiles) in the variables under study. To  
158 overcome this limitation, person-centered approaches allow **researchers** to identify  
159 homogenous subgroups of students based on target variables (Weller et al., 2020). Thus,  
160 person-centered analyses (e.g. latent profiles analysis) make it possible to examine the  
161 different combinations of both need-based experiences on different outcomes **in and**  
162 **outside of** PE.

163 To date, **a** few person-centered studies, based on need satisfaction and frustration,  
164 **have** been found in distinct domains (e.g. general, work, education, or sport) with  
165 different samples (e.g. youngsters, adults, or elderly) and regarding several  
166 wellness/illness outcomes (Li et al., 2022; Rouse et al., 2020; Tóth-Király et al., 2020).  
167 All these studies found between three and five need satisfaction and need frustration  
168 profiles with two common profiles characterized by high need satisfaction–low need  
169 frustration, and low need satisfaction–high need frustration, as well as a series of profiles  
170 supporting the asymmetrical relationship between need satisfaction and frustration (e.g.  
171 moderate need satisfaction–**moderate** need frustration). While the profile called “high  
172 need satisfaction–low need frustration” was associated in all studies with adaptive  
173 consequences, the profile called “low need satisfaction–high need frustration” was  
174 associated with maladaptive consequences (e.g. Li et al., 2022; Tóth-Király et al., 2020;  
175 Warburton et al., 2020). Further, profiles with moderate need satisfaction, paired with

176 moderate or low need frustration, tended to be less detrimental in maladaptive outcomes  
177 (Li et al., 2022; Rouse et al., 2020; Tóth-Király et al., 2020).

178 To the best of our knowledge, **there is only one** person-centered research based  
179 on students' need satisfaction and frustration in PE (Warburton et al., 2020). This study  
180 identified three need profiles in terms of composite scores for need satisfaction and  
181 frustration: 1) "high need satisfaction–low need frustration", 2) "moderate need  
182 satisfaction and need frustration", and 3) "low need satisfaction–high need frustration",  
183 which differed from each other in motivational outcomes within the PE context. While  
184 **the** "high need satisfaction–low need frustration" group of students was the highest in  
185 autonomous forms of motivation and the lowest in controlled forms of motivation and  
186 amotivation, the "low need satisfaction–high need frustration" profile was the most  
187 maladaptive in quality of motivation. Although this research made a valuable contribution  
188 to the field of PE, it analyzed need satisfaction and need frustration together, which may  
189 mask the role **that** each of them plays separately in the PE lesson. It is suggested that the  
190 three BPNs should be equally satisfied to have an additional source of quality of  
191 motivation and functioning in **PE lessons** (Mouratidis et al., 2015). Therefore, it is  
192 necessary to gain more in-depth knowledge of how the satisfaction and frustration of the  
193 needs for autonomy, competence and relatedness are independently combined in **PE**  
194 **lessons**. **In addition**, there is a need to expand evidence on the potential effects of these  
195 combinations of satisfaction and frustration of the three BPNs not only on motivation for  
196 PE (Warburton et al., 2020), but also on other learning-related outcomes **in and outside**  
197 **of** the PE lesson. This substantial body of evidence could be useful for PE teachers to  
198 know which profiles of need satisfaction and frustration may be the most and least  
199 adaptive in order to provide a need-supportive learning environment in PE lessons.

200 **The present research**

1  
2  
3 201 A first objective of the current study was to analyze within–person combinations  
4  
5 202 (i.e. profiles) of students’ perceptions of autonomy, competences, and relatedness need  
6  
7 203 satisfaction and need frustration in PE. Consistent with previous person–centered  
8  
9 204 research in PE (Warburton et al., 2020) and other domains (Li et al., 2022; Rouse et al.,  
10  
11 205 2020; Tóth-Király et al., 2020), we expected to find two profiles with the following  
12  
13 206 characteristics: 1) “high need satisfaction–low need frustration”, and 2) “low need  
14  
15 207 satisfaction–high need frustration”. Because need satisfaction and need frustration are  
16  
17 208 conceptualized as two distinguishable but related variables (Li et al., 2022; Vansteenkiste  
18  
19 209 et al., 2020; Warburton et al., 2020), we also expected to identify other need profiles  
20  
21 210 characterized by being moderate in either need satisfaction or frustration or both.

22  
23  
24  
25  
26 211 A second objective was to examine differences in these resulting need satisfaction  
27  
28 212 and frustration profiles in terms of outcomes in (i.e. quality of motivation, experiences,  
29  
30 213 and oppositional defiance) and outside of PE (i.e. PA intention, MVPA, and meeting PA  
31  
32 214 recommendations). Guided by SDT assumptions (Vansteenkiste et al., 2020) and  
33  
34 215 previous research in PE (Warburton et al., 2020) and other domains (Li et al., 2022; Rouse  
35  
36 216 et al., 2020; Tóth-Király et al., 2020), we hypothesized that the “high need satisfaction–  
37  
38 217 low need frustration” profile would be associated with more adaptive outcomes, while  
39  
40 218 the “low need satisfaction–high need frustration” profile would be related to the more  
41  
42 219 maladaptive outcomes in and outside of PE. Additionally, consistent with previous  
43  
44 220 studies (Haerens et al., 2015; Vasconcellos et al., 2020), we aimed to explore whether the  
45  
46 221 other identified profiles supported the possible protective effect of need satisfaction on  
47  
48 222 negative effects of need frustration to a certain degree under the study variables.

## 223 Method

### 224 Design and participants

225 An initial sample of 1118 Spanish secondary students, from five of eight public  
226 secondary school in a Spanish medium-sized city, took part in this cross-sectional study.  
227 A purposive sampling technique for recruitment and selection of participants was used.  
228 After verifying those students who submitted signed informed parental/guardian consent,  
229 the sample included 1087 (response rate: 97.23%) students. Data screening also suggested  
230 the need to eliminate 10 univariate ( $Z$ -scores over 3) and 15 multivariate (Mahalanobis  
231 distances with  $p < .001$ ) outliers before further analysis.

232 The final sample of this research consisted of 1062 secondary students (526 male  
233 and 536 female), aged between 11 and 18 years ( $M_{age}=14.15$ ,  $SD=1.51$ ) (for more details,  
234 see data analysis section). Most of students self-reported being white ( $n=943$ , 88.79%),  
235 while the remaining 11.21% ( $n=119$ ) belonged to different ethnic minorities. They were  
236 in the first ( $n=174$ , 16.38%), second ( $n=333$ , 31.36%), third ( $n=146$ , 13.75%), and fourth  
237 ( $n=162$ , 15.25%) grade of compulsory secondary education, and the first ( $n=247$ , 23.26%)  
238 grade of post-compulsory secondary education. In Spain, students receive two 60-minute  
239 compulsory and coeducational PE lessons per week. Classroom sizes range from 20 to 30  
240 students per classroom.

## 241 Instruments

### 242 Profile variables

243 **Need satisfaction and need frustration in PE.** To assess students' perceptions  
244 of need-based experiences in PE, the Spanish PE version (Zamarripa et al., 2020) of the  
245 Basic Psychological Need Satisfaction and Frustration Scale (Chen et al., 2015) was used.  
246 The instrument is headed by the stem "In my PE lessons..." and followed by 24 items  
247 (four per factor) measuring autonomy satisfaction (e.g. "I feel I have been doing what  
248 really interests me"), competence satisfaction (e.g. "I feel I can successfully complete  
249 difficult tasks"), relatedness satisfaction (e.g. "I experience a warm feeling with my

classmates I spend time with”), autonomy frustration (e.g. “I feel pressured to do too many tasks”), competence frustration (e.g. “I feel like a failure because of the mistakes I make”), and relatedness frustration (e.g. “I feel excluded from the group I want to belong to”). Items are scored on a 5-point Likert-type scale from 1 (strongly disagree) to 5 (strongly agree). In this study, the six-factor correlated model obtained an acceptable fit to the data:  $\chi^2(df=237)=997.78$ ,  $p<.001$ ,  $\chi^2/df=4.21$ ; CFI=.94; TLI=.93; SRMR=.049; RMSEA=.071(90%CI=.067–.074).

### 257 **Outcomes in PE**

258 **Motivation for PE.** To assess students’ perceptions of their behavioral regulation for PE, the Spanish version (Ferriz et al., 2015) of the Perceived Locus of Causality Scale (Goudas et al., 1994) was used. The instrument is headed by the stem “I participate in PE classes...” and is followed by 24 items (four per factor) measuring intrinsic motivation (e.g. “because I enjoy learning new skills”), integrated regulation, (e.g. “because I consider PE is consistent with my values”), identified regulation (e.g. “because I want to improve in PE”), introjected regulation (e.g. “because I want to get a good report in PE”), external regulation (e.g. “because I’ll get in trouble if I don’t”), and amotivation (e.g. “I don’t see why we should have PE lessons”). Items are scored on a 7-point Likert scale from 1 (strongly disagree) to 7 (strongly agree). In line with the SDT’s assumptions (Ryan et al., 2021) and previous research (Burgueño et al., 2019), this study supported a hierarchical three-factor model consisting of autonomous motivation (including primary-order factors of intrinsic motivation, integrated, and identified regulation), controlled motivation (including primary-order factors of introjected and external regulation), and amotivation ( $\chi^2[df=244]=818.251$ ,  $p<.001$ ,  $\chi^2/df=3.35$ ; CFI=.96; TLI=.95; SRMR=.036; RMSEA =.047 [90%CI=.044–.051]).

1  
2  
3 274 **PE experiences.** To assess students' perceived affective experiences in terms of  
4  
5 275 sensations, feelings and emotions in PE lessons, the question: "How are your experiences  
6  
7 276 in **the** PE subject?" was used, following previous research (Diloy-Peña et al., 2021). This  
8  
9 277 question is scored on a one-item 5-point Likert-type scale, including 1 (very bad), 2 (bad),  
10  
11 278 3 (regular), 4 (good), and 5 (very good).

12  
13  
14 279 **Oppositional defiance.** To assess students' perceptions of oppositional defiance  
15  
16 280 toward their PE teacher, the Spanish version (Abós et al., 2016) of the oppositional  
17  
18 281 defiance in PE questionnaire (Haerens et al., 2015) was used. The unidimensional  
19  
20 282 instrument is headed by the stem "During my PE lessons..." and includes four items (e.g.  
21  
22 283 "I have the tendency to rebel against the teacher's requests"). Each of them is scored on  
23  
24 284 a 5-point Likert-type scale from 1 (strongly disagree) to 5 (strongly agree). In this  
25  
26 285 research, the one-factor model obtained a good fit:  $\chi^2(df=2)=3.18, p=.204, \chi^2/df=1.59;$   
27  
28 286 CFI=1.00; TLI=1.00; SRMR=.009; RMSEA=.024 (90%CI=.000-.070).

### 29 287 **Outcomes outside of PE**

30  
31  
32  
33 288 **PA intention.** To assess students' perceptions of PA intention, the Spanish  
34  
35 289 version (González-Cutre et al., 2014) of the PA intention subscale from the Theory of  
36  
37 290 Planned Behavior Questionnaire (Hagger et al., 2009) was used. The subscale was headed  
38  
39 291 by the stem "During the next five weeks..." and included three items (e.g. "I plan to do  
40  
41 292 active sports and/or vigorous physical activities during my leisure time"). **Each of them**  
42  
43 293 **is scored** on a 7-point Likert-type scale from 1 (strongly disagree) to 7 (strongly agree).  
44  
45 294 In this research, one-factor model obtained a good fit:  $\chi^2(df=1)=5.84, p<.090, \chi^2/df=5.84;$   
46  
47 295 CFI=.99; TLI=.96; SRMR=.022; RMSEA=.056(90%CI=.046-.068).

48  
49  
50  
51 296 **MVPA levels.** To assess students' daily MVPA levels, the Spanish version (Aibar  
52  
53 297 et al., 2016) of the International Physical Activity Questionnaire–Short Form (IPAQ-SF;  
54  
55 298 Craig et al., 2003) was used. This Spanish version includes a modified version of the

1  
2  
3 299 IPAQ-SF protocol given the problems and difficulties detected by students in previous  
4  
5 300 studies. These modifications include: 1) groups of five students for each researcher to  
6  
7 301 resolve possible doubts, 2) explanation of the intensity of different types of activities with  
8  
9 302 images, and 3) daily recording of MVPA levels in the previous week to facilitate their  
10  
11 303 recall. This questionnaire has been shown to be valid and reliable (Aibar et al., 2016) to  
12  
13 304 assess MVPA levels (Craig et al., 2003). The IPAQ-SF modified version obtained much  
14  
15 305 better levels of agreement for MVPA levels between the questionnaire and  
16  
17 306 accelerometers than the previous version (Aibar et al., 2016). Daily MVPA time was  
18  
19 307 calculated by adding the daily time from Monday to Sunday and dividing it by seven  
20  
21 308 days.

22  
23  
24  
25  
26 309 **PA recommendations.** Meeting World Health Organization PA guidelines (i.e.  
27  
28 310 at least 60 minutes of MVPA/day) for adolescents were calculated (Bull et al., 2020) using  
29  
30 311 the previous calculated minutes/day of MVPA. Students were categorized as “yes” when  
31  
32 312 they met these PA guidelines, and “no” when did not meet these recommendations.

### 33 313 **Procedure**

34  
35  
36  
37 314 The researchers obtained approval from the Ethics Committee of University of  
38  
39 315 Extremadura (code: 153/2022), all permissions and authorizations from the management  
40  
41 316 team of each participating secondary school and written informed consent from parents  
42  
43 317 or guardians of each student. Participants took part in the research voluntarily and  
44  
45 318 anonymously and did not receive any compensation for their participation. They  
46  
47 319 individually completed a paper-and-pencil questionnaire in their classrooms without the  
48  
49 320 presence of their PE teacher so as not to influence their responses. The researchers  
50  
51 321 explained to the students that there were no correct or incorrect answers, as the study  
52  
53 322 focused on their perceptions and opinions about PE classes and PA-related behaviors. In  
54  
55 323 addition, the researchers were available to resolve any doubts that might have arisen  
56  
57  
58  
59  
60

1  
2  
3 324 **during** the completion of the questionnaires. The total duration of the data collection  
4  
5 325 process was approximately 30 minutes.  
6

7  
8 326 **Data analysis**  
9

10 327 While descriptive statistics (mean scores and standard deviations), McDonald's  
11  
12 328 omega reliability coefficient, and Pearson's correlations were computed for continuous  
13  
14 329 variables; descriptive statistics (percentage) and Spearman's correlations were estimated  
15  
16 330 for categorical variables. SPSS version 28 was used to conduct these analyses. Latent  
17  
18 331 profile analysis, based on autonomy, competence, and relatedness satisfaction and  
19  
20 332 frustration, and mean differences between profiles were run using Mplus version 8.4. **In**  
21  
22 333 **particular**, for identification of potential autonomy, competence, and relatedness need  
23  
24 334 satisfaction and need frustration profiles in PE, a latent profile analysis was run using  
25  
26 335 factor scores (with a mean of zero and a standard deviation of one). These factors were  
27  
28 336 generated from preliminary factor analysis to verify the psychometric properties of the  
29  
30 337 measures. All models, ranging from one to five profiles, were calculated by the robust  
31  
32 338 maximum likelihood estimator. Every model was computed with 5000 random sets of  
33  
34 339 start values, 1000 iterations and the 200 best solutions were retained to avoid suboptimal  
35  
36 340 local maximum (Muthén and Muthén, 1998-2017). The means and the variance of the  
37  
38 341 factors were freely estimated in all profiles (Muthén and Muthén, 1998-2017). For  
39  
40 342 selection of the best-fit profile solution, a series of model fit criteria were taken **into**  
41  
42 343 **account** (Weller et al., 2020). First, **the** bootstrapped Lo–Mendell–Rubin likelihood test  
43  
44 344 (LMR) was utilized to compare the fit of two models. Profiles were iteratively added to  
45  
46 345 identify the best-fit model. A significant LMR test ( $p<.050$ ) **indicates** that the target  
47  
48 346 profile solution fits the data better than a profile solution with one fewer profile (Weller  
49  
50 347 et al., 2020). Second, Akaike Information Criterion (AIC), Bayesian Information  
51  
52 348 Criterion (BIC), and Sample-Size Adjusted Bayesian Information Criteria (SSA-BIC)  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 349 were analyzed, displaying a better model fit with lower scores (Weller et al., 2020). Third,  
4  
5 350 entropy was also examined, indicating that values as low as .80 reflect an acceptable  
6  
7  
8 351 degree of accuracy of profile membership assignment (Weller et al., 2020). **Fourth**, it was  
9  
10 352 additionally considered that the number of adolescents **in** each profile had to be greater  
11  
12 353 than 5% of the total sample (Weller et al., 2020).

14 354 Finally, to test if need satisfaction and need frustration profiles differed **to** each  
15  
16  
17 355 other in motivation for PE, PE experiences, oppositional defiance in PE, PA intention,  
18  
19 356 and MVPA, the auxiliary “BCH” function, which is appropriate for continuous outcomes  
20  
21 357 of Mplus (Muthén and Muthén, 1998-2017), was used. For categorial outcomes, the  
22  
23 358 auxiliary “DCATEGORICAL” function of Mplus (Muthén and Muthén, 1998-2017) was  
24  
25  
26 359 applied to analyze differences in meeting PA recommendations between resulting need  
27  
28 360 satisfaction and frustration profiles. As the students’ motivational processes could be  
29  
30 361 affected by gender, age and school (Vasconcellos et al., 2020), distribution by gender,  
31  
32 362 age and school was analyzed to **control** for them across the tested latent profile models.  
33  
34  
35 363 The level of statistical significance was set at  $p<.05$ .

## 364 **Results**

### 365 **Descriptive statistics, reliability coefficients, and correlations among variables**

366 Table 1 shows mean scores above the midpoint of the measurement scale for  
367 autonomy, competence, and relatedness satisfaction, as well as autonomous motivation,  
368 PE experiences, and PA intention. **In addition**, there were mean scores below the midpoint  
369 of the measurement scale for autonomy, competence, and relatedness frustration,  
370 controlled motivation, amotivation, and oppositional defiance in PE. Furthermore,  
371 students **reported** 47.98 minutes/day of MVPA, and only 31.92% of them met PA  
372 recommendations. McDonald’s omega coefficient obtained values from .71 to .90,  
373 indicating a good level of reliability for the totality of variables (Viladrich et al., 2017).

1  
2  
3 374 On the other hand, the satisfaction of the three needs was positively correlated with  
4  
5 375 autonomous motivation in PE, PE experiences, PA intention, MVPA levels, and meeting  
6  
7 376 PA recommendations. Similarly, the frustration of each need was positively correlated  
8  
9 377 with controlled motivation, amotivation, and oppositional defiance in PE.  
10

11  
12 378 [INSERT TABLE 1 NEAR HERE, PLEASE]  
13

14 379 **Identification and interpretation of the latent autonomy, competence, and**  
15  
16 380 **relatedness need satisfaction and need frustration profiles in PE**  
17

18  
19 381 Fit indices, entropy, and model comparisons are reported in Table 2. Overall, AIC,  
20  
21 382 BIC, and SSA-BIC values were progressively lower, indicating a steady improvement of  
22  
23 383 the model, as additional profiles were added, with the lowest fit being in the 6-profile  
24  
25 384 solution. However, it should be noted that the 5-profile and 6-profile models had a profile  
26  
27 385 with less than 5% of the sample, and non-significant differences in LMR tests compared  
28  
29 386 to the 4-profile solution were found. In comparison with the 4-profile model, the 2-profile  
30  
31 387 and 3-profile models obtained higher parsimony values and significant differences in the  
32  
33 388 LMR test. Considering all the above, the 4-profile model was interpreted to represent the  
34  
35 389 most suitable, theoretically meaningful, and parsimonious solution.  
36  
37

38  
39  
40 390 [INSERT TABLE 2 NEAR HERE, PLEASE]  
41

42 391 The 4-profile model is depicted in Figure 1 and described in Table 3. Taking into  
43  
44 392 consideration the raw scores, profile 1 (n=625, 58.85%) was labeled as “high need  
45  
46 393 satisfaction–low need frustration” by being characterized by raw scores of 3.67, 4.03, and  
47  
48 394 4.33 out of 5 in autonomy, competence, and relatedness satisfaction, and of 1.87, 1.47,  
49  
50 395 and 1.12 out of 5 in autonomy, competence, and relatedness frustration. Profile 2 (n=176,  
51  
52 396 16.57%) was named “moderate need satisfaction–low need frustration” as it was  
53  
54 397 characterized by raw scores of 3.11, 3.44, and 3.77 out of 5 in autonomy, competence,  
55  
56 398 and relatedness satisfaction, and of 2.04, 2.17, and 2.09 out of 5 in autonomy,  
57  
58  
59  
60

1  
2  
3 399 competence, and relatedness frustration. Profile 3 (n=65, 6.12%) was labeled as  
4  
5 400 “moderate need satisfaction and frustration” by being characterized by raw scores of 3.10,  
6  
7 401 3.30 and 3.71 out of 5 in autonomy, competence, and relatedness satisfaction, and of 3.03,  
8  
9 402 2.64, and 2.73 out of 5 in autonomy, competence, and relatedness frustration. Profile 4  
10  
11 403 (n=196, 18.46%) was labeled “low need satisfaction–high need frustration” as it was  
12  
13 404 characterized by raw scores of 2.27, 2.74, and 1.16 out of 5 in autonomy, competence,  
14  
15 405 and relatedness satisfaction, and of 3.48, 3.09 and 3.34 out of 5 for autonomy,  
16  
17 406 competence, and relatedness frustration.

21 [INSERT FIGURE 1 NEAR HERE, PLEASE]

22  
23  
24 408 **Differences in students’ outcomes in and outside of PE between need satisfaction**  
25  
26 409 **and frustration profiles**

27  
28 410 Latent **profile** differences in students’ outcomes in PE and PA-related variables  
29  
30 411 **outside of PE** are displayed in Table 3. Prior to the analysis, a first overall mean equality  
31  
32 412 test found non-significant differences in gender ( $\chi^2=0.56, p=.454$ ), age ( $\chi^2=0.64, p=.424$ )  
33  
34 413 and school ( $\chi^2=1.65, p=.199$ ), suggesting that students were homogeneously distributed  
35  
36 414 across the four profiles according to these covariates.

37  
38  
39 415 For outcomes in PE, a second overall mean equality test was significant for  
40  
41 416 autonomous motivation ( $\chi^2=245.28, p<.001$ ), controlled motivation ( $\chi^2=98.19, p<.001$ ),  
42  
43 417 amotivation ( $\chi^2=213.58, p<.001$ ), experiences in PE ( $\chi^2=56.78, p<.001$ ), **and** oppositional  
44  
45 418 defiance in PE ( $\chi^2=90.101, p<.001$ ) between the four retained profiles. More specifically,  
46  
47 419 pairwise comparisons revealed that students from Profile 1 (i.e. high need satisfaction–  
48  
49 420 low need frustration) **scored** highest on autonomous motivation and PE experiences, as  
50  
51 421 well **as lowest** on controlled motivation, amotivation, and oppositional defiance in PE.  
52  
53 422 Conversely, students from Profile 4 (i.e. low need satisfaction–high need frustration)  
54  
55 423 scored lowest on autonomous motivation and PE experiences **and highest** on amotivation.  
56  
57  
58  
59  
60

1  
2  
3 424 Students from Profile 3 (i.e. moderate need satisfaction and frustration) showed the  
4  
5 425 highest score in controlled motivation. Students from Profile 2 (i.e. moderate need  
6  
7 426 satisfaction–low need frustration) scored significantly higher than students from Profile  
8  
9 427 3 in autonomous motivation and lower on amotivation. Likewise, students from Profile 2  
10  
11 428 did not significantly differ from students from Profile 3 in PE experiences and  
12  
13 429 oppositional defiance, the same way as students from Profile 3 were not significantly  
14  
15 430 different from students from Profile 4 in oppositional defiance.

16  
17  
18  
19 431 For outcomes outside of PE, a third overall mean equality test was significant for  
20  
21 432 PA intention ( $\chi^2=132.79$ ,  $p<.001$ ), MVPA ( $\chi^2=88.21$ ,  $p<.001$ ), and meeting PA  
22  
23 433 recommendations ( $\chi^2=72.19$ ,  $p<.001$ ) between the four identified profiles. More  
24  
25 434 specifically, pairwise comparisons showed that while students from Profile 1 obtained the  
26  
27 435 highest scores on PA intention, MVPA levels, and meeting PA recommendations,  
28  
29 436 students from the three remaining profiles were not significantly different in PA intention,  
30  
31 437 MVPA levels, and meeting PA recommendations.

32  
33  
34  
35 438 [INSERT TABLE 3 NEAR HERE, PLEASE]

### 36 37 439 Discussion

38  
39  
40 440 The purposes of this research were: 1) to examine the number of autonomy,  
41  
42 441 competence, and relatedness satisfaction and frustration profiles in PE; and 2) to analyze  
43  
44 442 differences in identified need satisfaction and frustration profiles (aim 1) in terms of  
45  
46 443 outcomes in and outside of PE. The main findings of this study are as follows: 1) need  
47  
48 444 satisfaction and need frustration in PE may co-occur to different degrees according to  
49  
50 445 students' perceptions; 2) the “high need satisfaction–low need frustration” profile showed  
51  
52 446 the most optimal patterns of outcomes in and outside of PE; 3) the “low need satisfaction–  
53  
54 447 high need frustration” profile yielded the least optimal pattern of outcomes in PE; 4) the  
55  
56 448 “moderate need satisfaction–low need frustration” profile tended to be more adaptive than  
57  
58  
59  
60

1  
2  
3 449 the “moderate need satisfaction–moderate need frustration” profile in outcomes in PE; 5)  
4  
5 450 the “moderate need satisfaction–low need frustration”, “moderate need satisfaction–  
6  
7 451 moderate need frustration”, and “low need satisfaction–high need frustration” profiles did  
8  
9 452 not differ from each other in outcomes outside of PE.

10  
11  
12 453 Concerning the first purpose, four profiles with varying levels of need satisfaction  
13  
14 454 and need frustration were identified, consistent with our hypothesis and previous research  
15  
16 455 (Tóth-Király et al., 2020). This number of profiles, nonetheless, contrasted with the three-  
17  
18 456 profile (Li et al., 2022; Warburton et al., 2020) and the five-profile (Rouse et al., 2020)  
19  
20 457 solutions reported by previous studies. A plausible explanation would rest on the: 1)  
21  
22 458 specific contextual differences between PE and other contexts (e.g. sport or work), 2) the  
23  
24 459 varied sample sizes ( $n=160$  to 2236) across the different studies, and 3) variability in the  
25  
26 460 composition of the profiles (i.e. composite or independent factors) in each study.  
27  
28 461 Specifically, some studies considered composite scores for need satisfaction and need  
29  
30 462 frustration profiles (Li et al., 2022; Rouse et al., 2020; Warburton et al., 2020), while in  
31  
32 463 another study, similar to this one, profiles were based on mean scores for autonomy,  
33  
34 464 competence, and relatedness satisfaction and frustration (Tóth-Király et al., 2020).

35  
36  
37 465 The results from the current research showed that two of the four profiles gathered  
38  
39 466 support for the asymmetrical relationship between need satisfaction and need frustration  
40  
41 467 (Vansteenkiste et al., 2020), such that there were two student groups who perceived high  
42  
43 468 need satisfaction–low need frustration and low need satisfaction–high need frustration.  
44  
45 469 This suggests that when students experience high pressure for task development  
46  
47 470 (autonomy frustration), a strong sense of inefficacy toward it (competence frustration),  
48  
49 471 and direct exclusion from their teacher and/or classmates (relatedness frustration) in PE  
50  
51 472 lessons, they are less likely to perceive high need satisfaction. Conversely, when students  
52  
53 473 perceive low need frustration, they would be prone to experience many opportunities and  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 474 choices for the ongoing task development (autonomy satisfaction), a strong sense of  
4  
5 475 mastery for the target task (competence satisfaction), and a close link with their teacher  
6  
7 476 and/or classmates in the PE lessons (relatedness satisfaction). These two profiles  
8  
9 477 accounted for slightly more than three-quarters (77.16%) of the students in this research.

10  
11  
12 478 The emergence of two profiles with moderate-to-low levels of need satisfaction  
13  
14 479 and need frustration featured approximately one-quarter (22.84%) of the participating  
15  
16 480 sample of the present study. The “moderate need satisfaction–moderate need frustration”  
17  
18 481 profile was often identified in previous studies (Li et al., 2022; Tóth-Király et al., 2020;  
19  
20 482 Warburton et al., 2020), while the “moderate need satisfaction–low need frustration”  
21  
22 483 profile arose as a “peripheral” or less common profile due to the specific contextual  
23  
24 484 features of PE (Howard et al., 2016). Both profiles, which are not simply characterized  
25  
26 485 by opposite perceptions of need satisfaction and frustration, underpinned the premise that  
27  
28 486 students could simultaneously experience both need satisfaction and need frustration  
29  
30 487 during PE lessons. This would mean that for students who experience certain  
31  
32 488 opportunities to choose their learning pace or the material for the task (autonomy  
33  
34 489 satisfaction), some sense of being good at it (competence satisfaction), and close links  
35  
36 490 with their teacher and/or classmates (relatedness satisfaction) during PE lessons, they  
37  
38 491 could also perceive that they have to perform tasks in a prescriptive manner (autonomy  
39  
40 492 frustration), inefficacy when performing wrong (competence frustration), and relative  
41  
42 493 exclusion by their peers and/or teacher from tasks at a given point (relatedness  
43  
44 494 frustration). These findings provide evidence in support of the clearly different nature of  
45  
46 495 need satisfaction and need frustration and the possible co-occurrence among students  
47  
48 496 within the PE lessons.

49  
50  
51 497 Regarding the second purpose, the four identified need profiles were significantly  
52  
53 498 different in outcomes in and outside of PE. Consistent with our hypotheses and following  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 499 previous person-centered research on PE (Warburton et al., 2020), the “high need  
4  
5 500 satisfaction-low need frustration” profile was the most adaptive, given that students  
6  
7 501 **scored highest** on autonomous motivation for PE, experiences in PE, PA intention,  
8  
9 502 MVPA levels, and meeting PA recommendation, as well **as lowest** on controlled  
10  
11 503 motivation, amotivation and oppositional defiance **in PE lessons. It is likely that when**  
12  
13 504 **students perceive choices (autonomy satisfaction), efficacy in ongoing tasks (competence**  
14  
15 505 **satisfaction), and positive links with their peer group (relatedness satisfaction), in the**  
16  
17 506 **presence of low perceived need frustration, they could participate in PE out of enjoyment,**  
18  
19 507 **interest, and because they personally value it (autonomous motivation).** In addition,  
20  
21 508 students' satisfaction of the three **BPNs** could reduce self-imposed and external reasons  
22  
23 509 (controlled motivation), the absence of intrinsic and extrinsic reasons (amotivation), **and**  
24  
25 510 **forceful** resistance against the teacher (oppositional defiance) in the PE lessons.  
26  
27 511 Complementary to variable-centered studies on PE (Di Battista et al., 2019; González-  
28  
29 512 Cutre et al., 2014; Gråstén et al., 2021), this person-centered **study** on PE provided  
30  
31 513 evidence indicating that high need satisfaction paired with low need frustration **in PE was**  
32  
33 514 **associated with higher** PA-related variables **outside of** PE. This could be since students  
34  
35 515 who perceive that their **BPNs** are satisfied and not frustrated in PE are more likely to be  
36  
37 516 more autonomously motivated not only in this subject, but also toward PA outside of  
38  
39 517 school. According to the trans-contextual model (Hagger et al., 2009), this link implies  
40  
41 518 that need satisfaction in PE **may transfer to out-of-school contexts, potentially resulting**  
42  
43 519 **in a greater intention to participate** in a wide variety of physical activities and,  
44  
45 520 consequently, higher MVPA levels and meeting PA recommendations.

51  
52  
53 521 In accordance with previous person-centered research on PE (Warburton et al.,  
54  
55 522 2020) and SDT assumptions (Vansteenkiste et al., 2020), the “low need satisfaction-high  
56  
57 523 need frustration” profile was the most maladaptive in terms of motivational quality in PE  
58  
59  
60

1  
2  
3 524 and negative PE experiences. According to SDT, a possible rationale **could** be that when  
4  
5 525 students **perceive feeling pressure and coercion to complete** the target tasks in a prescribed  
6  
7 526 manner (autonomy frustration), a strong sense of inefficacy **during ongoing** task  
8  
9 527 development (competence frustration), **and direct** rejection from their classmates and/or  
10  
11 528 teachers (relatedness frustration), in the presence of low need satisfaction, they are prone  
12  
13  
14 529 to have no autonomous or controlled reasons for PE participation (amotivation), **as well**  
15  
16  
17 530 **as negative PE experiences in practice.**

18  
19 531 Partially consistent with our hypotheses, our results also indicated that the  
20  
21 532 “moderate need satisfaction–low need frustration” and “moderate need satisfaction–  
22  
23 533 **moderate need** frustration” profiles could not only compensate **for** the detrimental effects  
24  
25 534 of need frustration on amotivation and oppositional defiance, but **also enhance**  
26  
27 535 autonomous motivation and positive experiences in PE lessons. It should be noted,  
28  
29 536 however, that the “moderate need satisfaction–low need frustration” profile was more  
30  
31 537 adaptive than **the** “moderate need satisfaction–**moderate need** frustration” profile, sugg  
32  
33 538 esting that when need satisfaction was moderate, relatively different levels of need  
34  
35 539 frustration were shown to be the trigger of more or less detrimental effects on students’  
36  
37 540 outcomes **inside of** PE. Moreover, **our findings indicated that moderate levels of need**  
38  
39 541 **satisfaction in PE could not attenuate negative effects of low–to–high levels of need**  
40  
41 542 **frustration in PE on students' outcomes outside of PE lessons.** Our results suggest that  
42  
43 543 students’ need satisfaction in PE does not seem to play a fully protective role against need  
44  
45 544 frustration in PE in the development of an active lifestyle outside **of** PE. **It is likely that**  
46  
47 545 **when students perceive low-to-moderate levels of need frustration, in the presence of**  
48  
49 546 **moderate need satisfaction, they could feel less intention to participate in a wide variety**  
50  
51 547 **of physical activities, engage in less PA levels, and therefore do not meet the PA**  
52  
53 548 **recommendations.**  
54  
55  
56  
57  
58  
59  
60

### 549 **Limitations and future perspectives**

550           Although this research **contributes** to the SDT literature in the PE context, several  
551 limitations should be recognized. First, the use of a cross-sectional design makes it  
552 impossible to infer causal relationships among the study variables. Additional  
553 longitudinal studies **should test** the temporal stability of the need satisfaction and  
554 frustration profiles **and analyze** the directionality between these profiles, as well as  
555 outcomes **in and outside of PE**. These endeavors may also allow **researchers** to explore  
556 within-person and between-person changes **in** need profiles over the academic year in  
557 PE. Second, the use of a purposive sample suggests interpreting the results with caution.  
558 It is recommended that in future research a representative sample of adolescents with  
559 different social and cultural **backgrounds**, educational **levels** (e.g. primary **education or**  
560 professional education), or **types** of school (e.g. private) participate in the study. Third,  
561 this research intentionally analyzed differences **in** need satisfaction and frustration  
562 profiles in motivational outcomes, oppositional defiance, and experiences in PE and PA-  
563 related variables outside **of** PE. Additional research may include potential antecedents of  
564 students' need-based experiences in PE lessons, such as need-supportive and need-  
565 thwarting behaviors from PE teachers, as well as other affective, cognitive, and behavioral  
566 outcomes **in and outside of PE**. Fourth, even though students were homogeneously  
567 distributed across the retained profiles according to gender, age and school, the belonging  
568 of every student to a **class** was not taken into account in this research and might have  
569 influenced the differentiated relationships between the retained need profiles and the  
570 target outcomes. Additional studies are needed to explore the multilevel character of the  
571 classroom in the associations of need satisfaction and need frustration profiles with  
572 outcomes in and **outside** of PE through person-centered approaches. Fifth, although all  
573 the questionnaires used are valid and reliable, all the variables in the study are self-

1  
2  
3 574 reported, so there could be a bias in the results found. Further, consistent with previous  
4  
5 575 research arguing that single-item instruments are considered appropriate (e.g., Matthews  
6  
7 576 et al., 2022), a single-item instrument was used to measure the students' perception of PE  
8  
9 577 experiences. Future studies should validate a multi-item scale to capture students'  
10  
11 578 experiences in PE lessons. Finally, future studies could use accelerometer-measured PA  
12  
13 579 to obtain a more accurate measurement of physical activity levels in and outside of PE.  
14  
15  
16

## 17 580 **Conclusions**

18  
19 581 The results of the present research identified four different profiles, based on  
20  
21 582 autonomy, competence and relatedness satisfaction and frustration, supporting the  
22  
23 583 premise that need satisfaction and need frustration are best conceptualized as separate and  
24  
25 584 distinguishable, but co-occurring experiences in PE. Further, the results displayed that the  
26  
27 585 “high need satisfaction–low need frustration” profile was the most adaptive in terms of  
28  
29 586 quality of motivation, experiences, and oppositional defiance (outcomes in PE), as well  
30  
31 587 as in PA intention, MVPA levels, and meeting PA recommendations (outcomes outside  
32  
33 588 of PE). Conversely, the “low need satisfaction–high need frustration” profile obtained the  
34  
35 589 most maladaptive in patterns of outcomes in and outside of PE. Overall, the results of this  
36  
37 590 research underline the importance of not only fostering students' need satisfaction in PE  
38  
39 591 lessons, but also minimizing need frustration since need satisfaction could not fully  
40  
41 592 attenuate the detrimental effects from low-to-high levels of need frustration to adaptive  
42  
43 593 outcomes in and, especially, outside of PE.
