

# **A Chemical Biology Approach to Control Endocannabinoid Biosynthesis**

**Mario van der Stelt, PhD**

Principal Investigator Medicinal Chemistry

Leiden University

Endocannabinoids play an essential role in human health and disease, regulating processes such as immunomodulation, energy balance and neurotransmission. Diacylglycerol lipase- $\alpha$  (DAGL- $\alpha$ ) is responsible for the production of the endocannabinoid 2-arachidonoylglycerol (2-AG) in the central nervous system. It is a potential drug target for the treatment of obesity and neurodegenerative diseases. Currently, there are no selective inhibitors and activity-based probes available for its study. The identification of selective DAGL- $\alpha$  inhibitors is hampered by a lack of assays that make use of endogenous DAGL- $\alpha$  activity in proteomes. Determination of the selectivity of the inhibitors in native tissues is important, because DAGL- $\alpha$  belongs to the class of serine hydrolases, containing more than 200 members with various physiological functions. Here, I will present a chemical biology approach to identify and characterize highly selective chemical probes to study the function of this protein both in vitro and in vivo.
